

Project Report

Problem Statement: The project is about a hotel management system, with a database for customers, written in C programming language.

Feature description: The project is a simulation of the database of a hotel called “Mr. Robot Hotel”, which has 30 rooms in 3 stories and contains the information of 20 customers.

The project contains 760 lines of code in C and a text file with information about 20 “customers” or records. Upon running the code, the application will show a login information, where after entering the username and password, a series of settings will be shown. The settings include viewing the database, searching for a particular record, adding a customer, deletion of a record, modifying a customer’s details, sorting the database, billing the customer by name, menus for food and room types, and an exit function.

The view function shows the entire database with 8 columns: Name, Email ID, Phone No., Check-in Date, Room Number, Nationality, Staying Period, and Status of payment. The search function searches for a particular record either by name, check-in date, room number or nationality. The add and delete functions add and delete a record from the database and updates the database in the text document respectively. The modify function searches for a record by name, then allows the user to edit the details of the corresponding record, and updates the database. The sort function displays the database in ascending order according to name, room number or staying period. Billing function asks for the name of the customer and displays the payment of their rooms according to their staying period. The Menus function shows the catalogues of different types of set menus of foods and rooms, and their prices; with the Food option displaying the bill due after choosing from the list and the latter option displaying the prices of the different rooms.

Limitations/Future Plans: The project is very limited to the options given and has no proper output for any options beyond the ones implemented. The database is strictly restricted to only what is shown in the program and very few things can be added without changing the codes drastically. The project can act as

a template for a proper hotel management system with a varied range of options to manipulate the database if it is made using C.
